

Prime slot: single-outcome prime editing replaced by PEtracer

3 edit sites per integration with an 8-mark alphabet, 5 integrations, 250 cells, 4 tree shapes x 5 seeds x 6 methods

Two changes are confounded here and the figure does not separate them: the mark alphabet (an edit records WHICH of 8 marks was installed, so independent edits at a site are usually distinguishable from shared ancestry) and the geometry and rate ladder (3 sites x 8 marks against 6 binary sites). Read this as 'the prime slot now models PEtracer', not as a measurement of what marks alone are worth -- that needs a marks_per_target = 1 run at identical geometry. Comb trees barely improve, so the gain is not uniform across lineage topologies.
