

# Seurat clusters against the lineage that produced the cells

64 terminal cells, 400 genes, 15 principal components. Top: lineage with tips coloured by cluster. Bottom: the same clusters on one shared UMAP.

Lineage groups for the ARI are obtained by cutting the tree to the same number of groups the clustering found, so agreement reflects assignment rather than matching granularity. The UMAP embedding is computed once and shared across panels; only the colouring changes.
