

Which clone 84 features the BASELINE simulation preserves, by rate model

10 integrations x 245 comparable sites, 250 cells; simulations masked with the real missingness pattern

Three rate models: a gamma at the shipped dispersion of 0.5, a gamma with the dispersion fitted, and per-target rates sampled from the measured per-site rates of the full 9,349-cell recording. Panels A and B are the marginals each rate model was calibrated on, so agreement there is a check that the calibration holds, not evidence about the model. Panels C to E were never calibrated: the generative model is free to get them wrong, and a mismatch says something about the model rather than the fit. Homoplasmy is measured without a tree, by four-gamete incompatibility, so it applies to the real data too.
