

BASELINE recorder: reconstruction accuracy against clone size

15444 clones from 171 organoids, 5 integrations, neighbour joining against the known clone tree

A

Accuracy against clone size

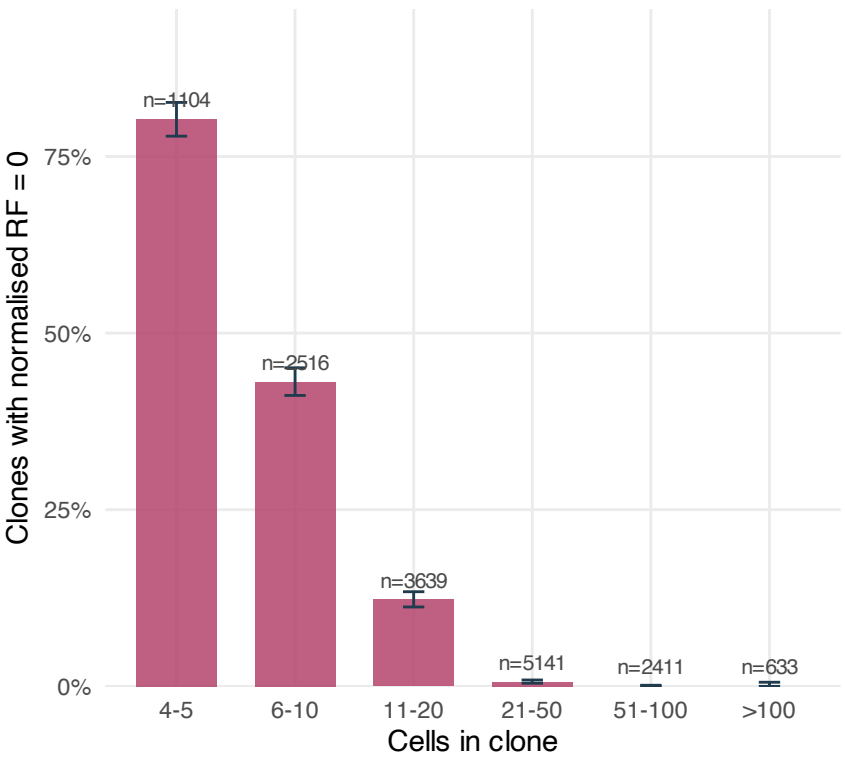

15444 clones; fill is clone count per bin, line is a loess fit over the raw values

B

Exactly recovered clones

Mean accuracy barely moves over this range; exact recovery collapses

C

Why signal and size cannot be separated here

Spearman rho = 0.97: bigger clones accumulate more edits, so an accuracy curve against character count restates this one
